

**YOU KNOW IT'S A BABY!!  
HAVE YOU EVER SEEN  
AN ULTRASOUND?  
OF COURSE YOU HAVE.  
CASE CLOSED!**

*Here are milestones  
of pre-natal development  
for when most chemical  
abortions takes place:*

- **5 weeks in the womb:** facial features are developing. Eye color is established.
- **6 weeks in the womb:** heart is beating, and the brain is divided into 3 parts.
- **7 weeks in the womb:** spontaneous movement begins. Yawning & sucking.
- **10 weeks in the womb:** finger prints and fingernails develop.
- **11 weeks in the womb:** all major organs are in place. Baby can smile.
- **13 weeks in the womb:** baby is active, but mom does not feel motion.
- **16 weeks in the womb:** baby can turn somersaults. Ovaries of girls forming.

**12 Weeks**

**TRANSFER YOUR  
PRESCRIPTIONS:  
GOODBYE CVS AND  
WALGREENS!!!**

**WHY?** Because these chains accepted the FDA offer to fill chemical abortion prescriptions across America. In March of 2024, CVS and Walgreens launched prescription sales to kill babies in the womb in California, Illinois, New York, Pennsylvania, Massachusetts, and Rhode Island.

Your first easy step is to visit the pharmacy you wish to use, such as Walmart, a grocery store pharmacy, etc. Not Target! All Target pharmacies are CVS! 😞  
Be prepared to provide prescription and insurance information. This pharmacy will process prescription transfers. Not difficult!

**You can do this! You should do this!**  
Later you should visit the Walgreens or CVS pharmacy and let a manager know WHY you moved your prescriptions.

Thank you for doing your part.  
We must be witnesses defending precious pre-born babies and their moms.

**PHARMACIES HAVE  
COMMITTED TO SELLING  
THE ABORTION PILL**

\* All Target pharmacies are CVS

**Snapshot of the  
pharmacy controversy**

- It is actually two pills. One brings death to the fetus. The second causes contractions that expel pregnancy remains.
- More than one million abortions each year are pill abortions. This is over 60% of all abortions.
- The pill abortion procedure can be traumatic, taking several difficult days. There are significant health consequences including the possibility of maternal death. Risks are elevated for pill abortions with little physician oversight, as with abortion pills dispensed by pharmacies.
- Pill abortions are often confused with "the morning after pill" (also called Plan B). Morning after pills are taken within a few days of sexual intercourse to block a pregnancy. Chemical abortion brings death to a developing fetus during the 5th to 15th week of pregnancy or even later.
- Pill abortion has different names. Life defenders call it a chemical abortion or use its original name of RU486. The pro-choice side calls it medical abortion or DIY abortion (do it yourself abortion).
- In March of 2024, CVS and Walgreens launched prescription sales to kill babies in the womb in California, Illinois, New York, Pennsylvania, Massachusetts, and Rhode Island. They plan to enter more states.
- There is one silver lining. If a mom changes her mind after taking the first pill, the abortion process can be reversed! More about this in another panel.
- We challenge the decision of CVS and Walgreens for breaking with the proud tradition of the pharmacy profession by agreeing to dispense pills intended for death rather than health.

# CHEMICAL ABORTION WHAT IS IT?

For a 4-minute animated video of chemical abortion, use this QR code or this link: [abortionprocedures.com/abortion-pill](https://abortionprocedures.com/abortion-pill)  
The video is narrated by former abortionist Dr. Noreen Johnson.

Chemical abortions result from a sequence of two drugs, Mifepristone and Misoprostol, taken about 48 hours apart.

Mifepristone blocks the woman's production of progesterone, which is needed for a healthy lining of the uterus. The lining breaks down, the flow of oxygen, blood, and nutrients to the fetus ceases, and the preborn baby dies.

The second drug, Misoprostol, triggers uterine contractions or the process of labor. The contractions eventually expel the dead fetus and other tissues of pregnancy. The woman often sees the dead fetus of 5 to 15 weeks of gestation intact. The fetal remains are typically flushed down a toilet.

At times, the fetus lives through the pill procedure! This is called a "failure" and requires a surgical abortion. The failure rate increases with the length of the pregnancy. The FDA assessment found a failure rate rising from 2% to 7.3% for pill abortions at 10 weeks.

Along with the failure rates, risks to the health and life of the mother also rises with later-term later term chemical abortions.

The original FDA approval in 2000 permitted pill only for up to 10 weeks. The original protocol also required an ultrasound exam, in-person counseling, pills taken in the presence of a physician and a final doctor visit within two weeks. If the final visit indicated failure, the doctor performed a surgical abortion.

**Health of the woman protocols are removed for pill abortions through pharmacy prescriptions.**

# JUST A FEW PILLS AND MANY DANGERS!

Misoprostol, the second pill in the sequence, causes severe cramping, contractions, and heavy bleeding, which forces the dead baby out of the mother's uterus. Contractions and bleeding can last from several hours to several days and be very painful. Many women also experience nausea, vomiting, diarrhea, abdominal pain, and headache. Even after the baby is expelled, the bleeding and spotting may continue for several weeks.

Maternal deaths have occurred, most frequently due to infection and undiagnosed ectopic pregnancies. Dozens of American women have died following pill abortions.

**Alyona Dixson, a 24-year-old wife and mother from Pahrump, Nevada, died days after obtaining a pill abortion at Planned Parenthood in mid-September of 2023.**

**She was treated in a hospital emergency center prior to her death. According to the County Coroner, the cause of death was "complications from a septic abortion".**

Heightened dangers arise from pharmacy chemical abortion pills. The pregnant woman receives no health exam, no ultrasound exam of her pregnancy, and no personal consultation with a physician.

- undetected ectopic pregnancy can cause fallopian tube rupture
- Rh-factor incompatibility causes immune response that can impair future pregnancies
- with no in-person screening, a sex trafficker can force an abortion upon a victim

# THIS IS AMAZING AND LIFESAVING!! **ABORTION PILL REVERSAL**

More than 5,000 children who were on their way to chemical abortions are now laughing and playing with their moms and dads.

**Here is what happens with this life saving "second chance" for baby and mom.**

The mother must change her mind soon after taking Mifepristone. Of course, she would not take Misoprostol pills, which would trigger labor contractions. The mom desiring abortion pill reversal must quickly get in touch with a knowledgeable physician, possibly through a pregnancy care center. The physician would place her on a regimen of doses of progesterone to counter Mifepristone's harm to the baby.

[abortionpillreversal.com](https://abortionpillreversal.com)  
877-558-0333

The reversal process is not rocket science. The protocol was created by Dr. George Delgado. Like most obstetricians, Dr. Delgado was familiar with prescribing extra progesterone for pregnant moms when natural production of progesterone was low. This condition is a significant risk factor for miscarriage. He reasoned that what worked to counter low progesterone resulting from natural body function would also work to counter the impact of mifepristone. When a mom changed her mind in favor of life for her baby, she could be given doses of progesterone to offset the killing impact of Mifepristone. This could sustain the vital needs of the baby and continue the pregnancy for a healthy delivery. Attempts to achieve abortion pill reversal are successful in about two-third of cases.
